ABSTRACT

In studying light and image transfer in sea water the influence of Fresnel surface reflection is as significant as scattering and absorption phenomena. In these cases a knowledge of the reflective properties of sea surface at different wind speeds is very important. At present, little is published about these properties. We present here results of numerical modeling of Fresnel light reflection coefficient of sea water as a function of solar zenith angle and wind speed. The ray-tracing computer model was developed to generate wave slopes and elevations. In order to generate a realistic sea surface the model used Paul Hwang wave height spectrums. The final result of this paper is a simple equation and very fast FORTRAN code to calculate Fresnel reflection coefficient of wavy water surface and specular part of remote sensing reflectance.

INTRODUCTION

The optical remote sensing reflectance of the ocean consists of two parts: one that is connected to the specular reflection of light from wavy water surface, and the second one that is due to the diffuse light ascending from the water. The information about the optical state of water body is contained in the internal light coming from the sea. In order to precisely estimate the second internal component of the remote sensing reflection we need an approach to precisely estimate the first, specular reflected component of light.

This presentation explains a new and very fast algorithm to compute specular reflection of solar light from the wavy water surface. The specular light reflected from the water surface consists of two parts. The first part is due to the Fresnel reflection from a wind-roughened surface, and the second one is due to the reflection by whitecaps. The Fresnel part of reflection was computed using a Monte Carlo method. The roughness of water surface was realistically modeled with the use of surface wave energy distributions by Paul Hwang. The resulting reflection coefficient of light by a water surface was obtained by averaging over billion realizations of reflection coefficient. Results of these calculations are expressed as a very precise regression that connects Fresnel reflection coefficient to the solar angle and wind speed.

The proposed algorithm is implemented as a very fast FORTRAN code (See Appendices A and B) to compute a specular reflection component of the remote sensing reflectance.

SPECULAR PART OF REMOTE SENSING REFLECTANCE

The specular part of remote sensing reflectance consists of two parts, the first one, connected with Fresnel reflection coefficient of light from rough (wavy) water surface \( r_F \), and the second one, related to reflection of light from sea foam or whitecaps \( r_{SF} \). It can be expressed as a following expression:

\[
r_S = r_F + r_{SF},
\]

(1)

The reflection by sea foam can be regarded as Lambertian and is expressed as follows:

\[
r_{SF} = f(u) A_F / \pi,
\]

(2)

where \( A_F \) is an albedo of the foam \( (A_F = 0.6) \), and \( f(u) \) is a portion of the sea surface covered with whitecaps (foam), \( u \) is a wind speed. The function \( f(u) \) is defined by the following regression (Frouin, 1996):

\[
f(u) = \begin{cases} 
0.000012 u^{3.3} & , \quad u \leq 9 \text{ m/s}, \\
(0.225 u - 0.99) u^3 & , \quad u > 9 \text{ m/s}.
\end{cases}
\]

(3)

The Fresnel portion of the remote sensing reflectance is defined by the following equation:

\[
r_f = [1 - f(u)] R_F(u,Z_S),
\]

(4)

where \( Z_S \) is an angle of incidence equal to a solar zenith angle for flat water surface. When wind speed is equal to zero, there are no foam on a sea surface \( (f(u) = 0) \) and foam-related part of remote sensing reflectance is equal to zero \( r_{SF} = 0 \), the surface is flat and \( r_f = R_f^0(Z_S) \), where \( R_f^0(Z_S) \) is Fresnel specular reflection coefficient from flat water surface, defined by the following equation:

\[
R_f^0(Z_S) = \frac{1}{2} \left[ \frac{\cos Z_S - \sqrt{n_w^2 - \sin^2 Z_S}}{\cos Z_S + \sqrt{n_w^2 - \sin^2 Z_S}} \right]^2 + \frac{\left( n_w^2 \cos Z_S - \sqrt{n_w^2 - \sin^2 Z_S} \right) ^2}{n_w^2 \cos Z_S + \sqrt{n_w^2 - \sin^2 Z_S}}
\]

(5)

here \( n_w \approx 1.341 \) is a refractive index of water.

When wind started to blow, it roughens the water surface and the situation becomes more complex; we need to average expression (5) over incidence angles. There are different approaches to accomplish this procedure: 1) we can use a Cox and Munk (1954) sea water slope distribution, or 2) we can use Monte Carlo method to generate wave slopes using wave energy spectrums taken from experimental measurements (Haltrin, McBride III, and Weidemann, 2000). The second approach is more complex and time-consuming, but it gives better results, especially for remote sensing applications. To compute specular part of remote sensing reflectance in this paper we used the second approach.
COMPUTATIONS OF FRESNEL REFLECTION COEFFICIENT

To generate sea water surface slopes we used a Monte Carlo program described in Haltrin, McBride III, and Arnone (2001). The values of sea surface orientation allow us to compute light reflection coefficient in each pixel of the sample surface. Averaging over $M \times M$ spatial and $L$ temporal realizations gives an average Fresnel reflection coefficient for each value of wind speed $u$ and zenith angle $Z_S$. To compute actual values of Fresnel reflection coefficient we used the Paul Hwang (1997) spectrum. This spectrum is specifically tailored for remote sensing problems to produce correct values of mean square slopes of ocean waves.

The generated realizations of Fresnel reflection coefficients have been averaged over $100 \times 100$ pixels of sample sea surface areas and 80 time realizations to produce resulting angular distributions of Fresnel reflection coefficient. The values of elevations and orientations in each pixel have been obtained using one million computations, 1000 realizations for flat sine waves and 1000 significant points of wave number $k$ in energy spectrum range. To generate random numbers we used the Mersenne Twister random number generator (Matsumoto and Kurita, 1992, 1994) capable to produce evenly distributed random numbers in a cube of 626 dimensions. So each value of Fresnel reflection coefficient for any value of wind speed and zenith angle represents an average value of 800 billion individual computations.

FRESNEL REFLECTION COEFFICIENT BY WAVY WATER SURFACE

The results of extensive Monte Carlo computations are compactly represented as a following regression equation (Haltrin, McBride III, and Arnone, 2001):

$$R_r(u,Z_s) = a_0(u) + R_r^0(Z_s)\left\{a_1(u) + R_r^0(Z_s)\left[a_2(u) + a_3(u)R_r^0(Z_s)\right]\right\},$$

(6)

where $R_r^0(Z_s)$ is a Fresnel reflection coefficient of flat water surface given by Eq. (5), and wind-speed-dependent coefficients $a_i(u)$ are given by the following equations:

$$a_0(u) = 0.001(6.948431 - 1.912076u + 0.03654833u^2), \quad r^2 = 0.9997,$$

(7)  

$$a_1(u) = 0.7431368 + 0.0679787u - 0.0007171u^2, \quad r^2 = 0.9996,$$

(8)  

$$a_2(u) = 0.5650262 + 0.0061502 - 0.0239810u + 0.10695u^3, \quad r^2 = 0.9995,$$

(9)  

$$a_3(u) = -0.4128083 - 0.1271037u + 0.0283907u^2 - 0.0011706u^3, \quad r^2 = 0.9991.$$  

Equations (1)-(6) represent a complete algorithm to compute the specular part of remote sensing reflectance. This algorithm is programmed in FORTRAN and presented in Appendices A and B.
